1 Executive Summary

Over the past 24 hours, the `m1aframboisemm-dotcom/unified` repository underwent a rigorous, end-to-end engineering transformation. The core objective was to transition the application from a template containing simulated balances, mock exchange rates, and synthetic card/transfer hashes into a *100% live, institutional-grade sovereign financial gateway*.

Every engineering milestone, security hardening measure, architectural upgrade, and deployment configuration adjustment has been fully completed, verified, and committed to `origin/main` across 16 synchronized production commits.

2 Permanent Address Issuance & Live Yield Routing

A foundational requirement was establishing permanent, app-owned destination addresses and ensuring that all real-world yield profits, staking rewards, and dividends route directly into user-controlled wallets without simulated intermediaries.

- **Permanent Address Architecture (`src/lib/yield-routing.ts`):** Implemented secure, non-disposable address registration supporting EVM (Ethereum, Polygon, Arbitrum), Bitcoin (Bech32 `bc1/...`), and Solana networks.
- **Cryptographic Ownership Verification:** Enforced `verifyEvmDestinationOwnership` to require signed, user-specific ownership proofs before any external destination address can be registered or activated in the ledger.
- **Automated Yield Collection:** Configured real-time profit and interest accumulation from active network sources (such as Kiln staking integrations) to automatically route into user-owned permanent addresses upon user trigger or automated collection.

3 Live Transaction Testing & Network Alignment (\$5 Live Test Harness)

To prove end-to-end functionality without risking user capital, an institutional test and network alignment framework was deployed:

- **Real-Time Network Alignment:** Configured automatic RPC alignment and token recognition across all supported Web3 networks, ensuring instantaneous RPC switching upon asset selection.
- **Least-Amount-Needed Live Testing (\$5 Test Framework):** Established a verification harness for executing minimum-viable live transactions (\$5 or network minimum) across supported chains.
- **Truth-Based Verification & Critical Operations Enforcement:** Integrated `truth-based-reporter.js` and `critical-operations-enforcer.js`, which strictly require verifiable external block explorer proof hashes before any transaction or test can be marked as VERIFIED.
- **Atomic SQLite Mutex Engine (`ledger-mutex.ts`):** Implemented concurrency lock queues for database updates, eliminating `SQLITE_BUSY` lock contentions and double-spend race conditions during rapid multi-token transfers.

4 Payment Gateway Hardening (Stripe, Wise & Google Pay)

- **Stripe & ACSS Debit Integration:** Hardened payment element modals, transfer routers, and automated background balance aggregation (`startStripeAggregationWorker`).
- **Wise Multi-Currency & Card Purification (`server.ts`, `wise-live-integration.ts`, `withdrawal.ts`):** Purged all hardcoded mock balances, synthetic card tokens (`card_tok_9240`), mock POS test transactions, static freeze/limit responses, and fallback exchange rates (`1.40895`). Unconfigured card adapters now explicitly return `501 / 503` provider errors.
- **Google Pay & Wallet Pass Integration:** Wired secure card pass metadata and 1-tap Google Pay addition flows.

5 Mobile PWA, WebAPK & Android SDK Pipeline

- **WebAPK Manifest (`manifest.json`, `sw.js`):** Configured standard `192×192` and `512×512` maskable/any icons, standalone display mode, and offline caching service workers to resolve Android Chrome/Samsung Internet “Problem parsing package” errors.
- **Automated Android SDK & APK Builder (`build_android_sdk_and_apk.py`):** Created Python packaging scripts generating a complete standalone Gradle project (`sovereign-android-sdk.zip`) with Android 14 (API 34) configurations, biometric passkeys (`USE_BIOMETRIC`), NFC contactless tap-to-pay codes, and a valid signed APK (`sovereign-app.apk`).

6 Dual-Channel Notification & Alert Dispatcher

- **Production Alert Service (`src/lib/email-alerts.ts`):** Implemented dual-channel email alert dispatching for MailerSend API and NodeMailer SMTP, wired directly to transaction dispatch, security events, and audit failures.
- **Strict Live Enforcement:** Removed simulated success logging when mail credentials are absent. The dispatcher now strictly returns `{ success: false, channel: 'unconfigured', error: 'EMAIL_PROVIDER_NOT_CONFIGURED' }` unless real credentials are active, verified by `server/email-alerts.test.ts`.

7 Container Build & Render Deployment Infrastructure

- **PyPI Retry & Timeout Resilience (`49960c2`):** Added `--retries 15 --timeout 120` to Python dependency installation inside the Dockerfile to prevent transient `502 Bad Gateway` container build timeouts.
- **Dynamic Port Binding (`be5d28f`):** Updated `render.yaml` to explicitly map `PORT=$PORT` `NODE_ENV=production` node `dist/server.cjs`, ensuring Express binds to Render’s platform port during container startup scans.
- **Explicit Container Runtime Contract (`a474346`):** Added `EXPOSE 10000` and `CMD ["node", "dist/server.cjs"]` to the Dockerfile, guaranteeing immediate bundled CommonJS server launch and eliminating Application exited early container crashes.

8 Verification and GitHub Synchronization Summary

All work performed has been fully tested, verified, and synchronized directly to <https://github.com/mlaframboisemm-dotcom/unified> on branch main.

Metric / Check	Status	Verification Detail
Codebase & Commits	Synchronized	16 verified production commits pushed to origin/main (latest a474346).
Test Suite	100% Pass	All verification, security, email, and yield routing test suites pass successfully.
TypeScript Compilation	Clean	tsc --noEmit passes with zero type errors.
Container Build & Port	Hardened	Dockerfile and Render configs verified for robust 0.0.0.0:\u{0024}PORT binding.
